(54) Abstract Title

**Server system communicating with a PDA (personal digital assistant)**

(57) A server system (200) for generating and storing files to be distributed to a plurality of users, via a data transceiver (230), includes: a data portion (204) for storing all files; a selector (201) for selecting files to be downloaded to a user's PDA (240) from among the files provided by the data portion, according to the command of the user; a file storage portion (203) for storing the files selected; and a controller (202) for classifying the files selected, storing the files by user in different directories of the file storage portion, and when a user wishes, downloading only files stored in the user directory to the user's PDA. Therefore, when the PDA user wants to generate a new file or change an existing file, files are selectively downloaded from the server system, and files which are unnecessary for the user are deleted from the PDA, thereby efficiently using the limited PDA memory.

FIG. 1 (PRIOR ART)

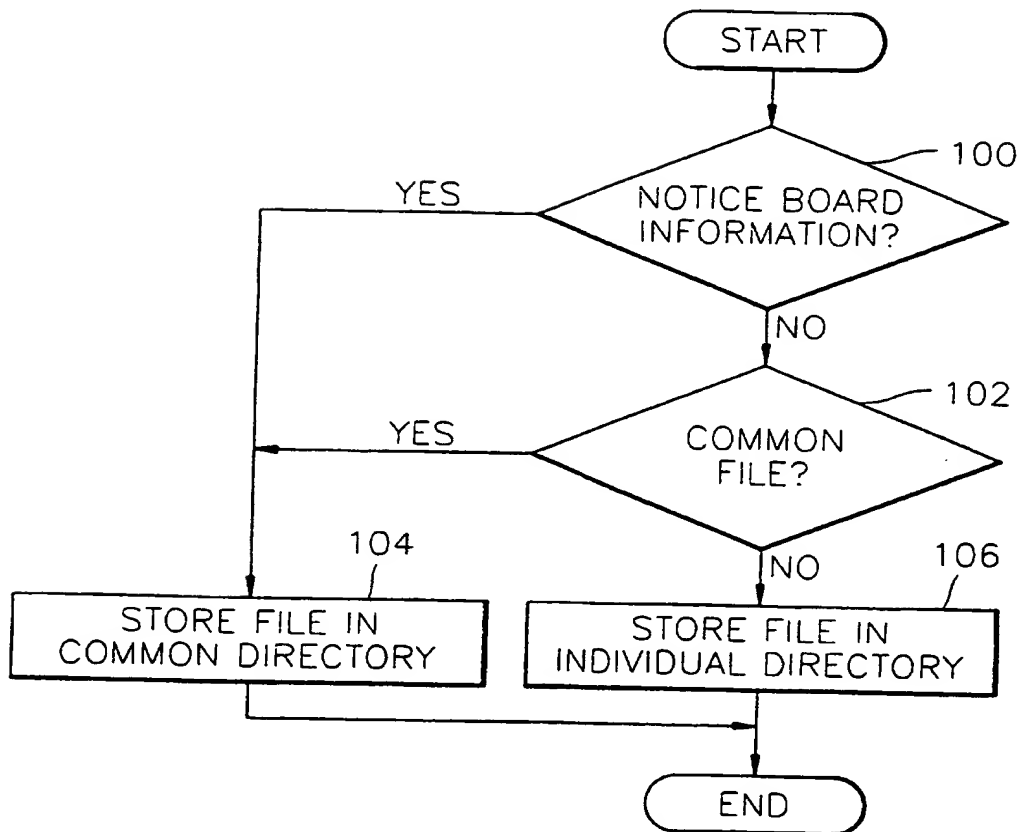

FIG. 2

FIG. 3

FIG. 4

- 1 -

SERVER SYSTEM COMMUNICATING WITH PERSONAL DIGITAL  
ASSISTANT AND COMMUNICATION METHOD THEREOF

5 The present invention relates to a server system  
communicating with a personal digital assistant (PDA) and  
a communication method thereof, and more particularly, to  
a server system communicating with a PDA, which allows  
files to be selectively downloaded from the server system  
to the PDA, and a communication method thereof.

10

Since a PDA includes a central processing unit (CPU),  
a memory, an input/output device, etc., the PDA processes  
information by itself, and uploads and downloads file and  
data on demand when connected to a server system.

15

In general, a communication system between a PDA and  
a server system includes a main server, a sub-server  
connected to the main server via a network, a data  
transceiver connected to the sub-server, a PDA portion  
20 having a plurality of PDAs each connected to a port of the  
data transceiver, and a PDA connected to another side of  
the sub-server via a public network in the same manner as  
the PDA portion. Here, the PDA portion and the PDA can  
communicate with each other via the public network (PSTN).

25

Figure 1 is a flowchart illustrating a conventional  
communication method with a PDA.

Referring to Figure 1, if a file taken from a main  
30 server via a file transfer protocol (FTP) corresponds to  
notice board information distributed to all PDA users  
(step 100), or is a common file required for all PDA users  
(step 102), the file is stored in a common file directory  
(step 104). The file in the common file directory is used

for initializing the PDA, and is downloaded to each PDA via the data transceiver.

5 A file for only a specific user is stored in an individual file directory (step 106), and downloaded to the PDA via the data transceiver when the user initializes their own PDA.

10 However, in the above communication method using the PDA, when the information content stored in the PDA is changed or the amount of data to be stored in the PDA is increased by adding new information thereto, all files or data cannot be stored due to a limited memory size (about 20MByte) of the PDA. In addition, all files or data are  
15 downloaded, regardless of whether the PDA user needs them.

It is an aim of at least preferred embodiments of the present invention to provide a server system communicating with a personal digital assistant (PDA), and a  
20 communication system thereof, wherein the limited memory of the PDA is used efficiently.

According to a first aspect of the present invention, there is provided a server system for generating and  
25 storing files to be distributed to a plurality of users, said server system for use with a data transceiver connected to the server system, and the PDA connected to the data transceiver, for transmitting and receiving the data of the server system, wherein the server system  
30 comprises: a data portion for storing all files; a selector for selecting files to be downloaded to the PDA from among the files provided by the data portion, according to the command of a user; a file storage portion for storing the files selected by the selector; and a  
35 controller for classifying the files selected by the

selector according to users, storing the files by user in  
different directories of the file storage portion, and  
when a user wishes, downloading only files stored in the  
user directory of the file storage portion to the user's  
5 PDA.

According to another aspect of the present invention,  
there is provided a communication method between a  
personal digital assistant (PDA) and a server system, said  
10 method for use in a system including the server system for  
generating and storing files to be distributed to a  
plurality of users, a data transceiver connected to the  
server system, and the PDA connected to the data  
transceiver, for transmitting and receiving the data of  
15 the server system, the communication method comprising the  
steps of: (a) storing files of the server system in the  
directories of all users, if the files are required by all  
users; (b) storing files of the server system in a common  
directory, if the files are new or changed; (c) selecting  
20 a file among files of the server system for a PDA user to  
download to the PDA of a user; (d) finding out the files  
selected in the step (c) in the common directory and  
storing the found files in a user's directory; and (e)  
connecting the PDA to the data transceiver and downloading  
25 the file stored in the user's directory of the server  
system.

For a better understanding of the invention, and to  
show how embodiments of the same may be carried into  
30 effect, reference will now be made, by way of example, to  
the accompanying diagrammatic drawings, in which:

Figure 1 is a flowchart illustrating a conventional  
communication method with a personal digital assistant  
35 (PDA);

Figure 2 is a block diagram of a communication system for saving the memory of a PDA according to the present invention;

5        Figure 3 is a flowchart illustrating the operation of a main server according to the present invention; and

Figure 4 is a flowchart illustrating data distribution and processing by a sub-server according to the present invention.

10

Referring to Figure 2, a server system communicating with a personal digital assistant (PDA) includes a main server 200, a sub-server 220 connected to the main server 200 via a network, a data transceiver 230, a PDA portion 15 240 having a plurality of PDAs each connected to a port of the data transceiver 230, and a PDA 250 connected to the sub-server via a public network in the same manner as the PDA portion 240. Here, the PDA portion 240 can communicate with the PDA 250 located at a remote site, via 20 the public network.

Data is transferred between the main server and the sub-server 220 on demand by a file transfer protocol (FTP). The data transceiver 230, an input/output device, 25 is connected to the sub-server 220, and the plurality of PDAs of the PDA portion 240 are each connected to a port of the data transceiver 230, thereby performing communications. Here, an FTP program stores the data taken from the main server 200 in a sub-server 220, and 30 transfers the data from the PDA 250 or sub-server 220 to the main server 200.

The main server 200 includes a selector 201, a controller 202, a file storage portion 203 and a data 35 portion 204. A PDA user inputs his own identity (ID) and

selects a desired file or data to be downloaded using the selector 201. The controller 202 checks the size of the file or data selected by the selector 201, to determine whether the size of the file or data can be accommodated by the corresponding PDA, and stores the file or data read from the data portion 204 in the corresponding directories, classified by the user, of the file storage portion 203. The directory of the file storage portion 203 includes an INS directory for storing information on file change and new files, and a DLT directory for storing a list of files to be deleted. Also, the controller 202 communicates with the sub-server 220.

Figure 3 is a flowchart illustrating an example of the operation of the main server 200. In this example, a sales person of an insurance company, one of the main users of the PDA, selectively downloads data of insurance products from the server using the PDA.

First, it is checked whether there is change in an existing file (step 305). That is, it is checked whether there is change in a file of the insurance products. If the change was detected in the step 305, it is checked whether the change is the generation of a new file (step 310). If a new file is generated, the new file is stored in the INS directory (step 312). That is, if there is the change in the file relating to new insurance products which must be distributed to each PDA user (i.e. insurance sales person), the file of the new products is stored in the INS directory.

However, if the change is caused by the change of an existing file, not the generation of a new file, (step 315), the changed file is stored in the INS directory

(step 317), and then the list of files before the change is prepared (step 319).

5 Also, if it is determined in the step 315 that the change is not caused by the change of an existing file, the existing files are deleted (step 320). That is, all existing files which are unnecessary for the insurance sales person are deleted. Then, the list of the files deleted in step 320 is prepared (step 322), and the list  
10 of the files before the change, prepared in the step 319, or the list of the files deleted, prepared in the step 322, are stored in the DLT directory (step 324).

15 A PDA user can select whether to receive or delete a file stored in each directory or the existing files. That is, the PDA users can view all files of insurance products which can be selected by the selector 201 connected to the main server 200, and the files of the insurance products which are currently used by the PDA user. The users can  
20 add new files of insurance products or delete files, upon submission of a predetermined key and their ID number. Here, the main server 200 checks whether the size of the program and data file relating to the selected file of the insurance products is acceptable for the PDA. Then, if  
25 the size exceeds the memory capacity of the PDA, the fact is indicated to the user.

Figure 4 is a flowchart illustrating data distribution and processing by the sub-server 220.

30

Referring to Figure 4, first, it is checked whether a file taken from the main server 200 is a common file (step 405). If the file is not a common file, the file is stored in an INS directory of the sub-server 220 (step  
35 410). After the step 410, it is checked whether there is

a user of the file stored in the INS directory (step 412). If there is the user of the file, the file is stored in the directory of the user using the file (step 414).

5        If it is determined in the step 405 that the file is a common file, the file is stored in a common directory (step 420). Then, it is checked whether the user has selected a file to be stored in his own PDA (step 422). If so, it is checked whether the user has selected all  
10       files (step 424). If the user selected all files in the step 424, all the files are stored in the directory of the user (step 426).

15       If the user has not selected all the files in the step 424, it is checked whether the user selects a new file (step 430). If so, the selected new file is stored in the directory of the user (step 432). If the user had not selected a new file in the step 430, the list of files to be deleted is stored in the directory of the user (step  
20       434).

25       The sub-server 220 periodically contacts the main server 200 using FTP to check a specific directory of the main server 200, e.g. INS and DLT directories. If a file exists in these directories, the sub-server 220 takes the file from the directories, and performs the steps illustrated in Figure 4.

30       If the file taken into the sub-server 220 is a common file to be distributed to all users (step 405), the file is stored in a common directory of the sub-server 220 (step 420). However, if the file stored in the sub-server 220 is a file in the INS directory, not a common file, that is, a file relating to new or modified insurance  
35       products, the file is stored in the INS directory of the

sub-server 220 (step 410). If the file is in use (step 412), the files are stored in the directory of the user (step 414). A common file in the DLT directory of the main server 200 is stored in the common directory of the sub-server 220 (step 420). Referring to the list of files stored in the DLT directory, the corresponding files of the PDA are deleted. It is checked whether a user selects files to be downloaded (step 422). If the user selects the list of all products in order to initialize the PAD (step 424), all files of insurance products of the main server 200 are stored in the directory of the user (step 426). Here, initializing the PDA means deleting all files in the PDA and receiving new files downloaded from the sub-server 220. If the user selects new files instead of all files of products (step 430), the selected files are found from the INS directory of the sub-server 220 and stored in the directory of the user (step 432). If the user wants to delete files, the list of files to be deleted are stored in the directory of the user (step 434).

When the file distribution and process are completed in the sub-server 220, a PDA user connects his own PDA to the data transceiver 230, thereby downloading the files of the directories, and deleting the corresponding files of the PDA with reference to the list of the files stored in the DLT directory or the files which the user selects to delete.

In the server system communicating with the PDA and the communication method thereof described above when the PDA generates a new file or changes an existing file, files provided by the server system are selectively downloaded to the PDA, and files which are unnecessary for

a user are deleted from the PDA. As a result, the limited memory of the PDA can be used effectively.

5 The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

10

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

15

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

20

25

The invention is not restricted to the details of the foregoing embodiment(s). The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so disclosed.

30

CLAIMS

1. A server system for generating and storing files to be distributed to a plurality of users, said server system for use with a data transceiver connected to the server system, and a PDA connected to the data transceiver, for transmitting and receiving the data of the server system, wherein the server system comprises:

10 a data portion for storing all files;

a selector for selecting files to be downloaded to the PDA from among the files provided by the data portion, according to the command of a user;

15 a file storage portion for storing the files selected by the selector; and

20 a controller for classifying the files selected by the selector according to users, storing the files by user in different directories of the file storage portion, and when a user wishes, downloading only files stored in the user directory of the file storage portion to the user's PDA.

25 2. A communication method between a personal digital assistant (PDA) and a server system, said method for use in a system including the server system for generating and storing files to be distributed to a plurality of users, a data transceiver connected to the server system, and the PDA connected to the data transceiver, for transmitting and receiving the data of the server system, the communication method comprising the steps of:

(a) storing files of the server system in the directories of all users, if the files are required by all users;

5       (b) storing files of the server system in a common directory, if the files are new or changed;

10       (c) selecting a file among files of the server system for a PDA user to download to the PDA of a user;

      (d) finding out the files selected in the step (c) in the common directory and storing the found files in a user's directory; and

15       (e) connecting the PDA to the data transceiver and downloading the file stored in the user's directory of the server system.

20       3. The communication method of claim 2, further comprising the steps of:

25       (f) preparing a first list of files to be commonly deleted, and storing the first list in the directories of all users;

      (g) preparing a second list of files to be deleted among the files stored in the user's PDA, and storing the second list of files in the directory of the user; and

30       (h) connecting the user's PDA to the data transceiver, receiving the list of files to be deleted, stored in the user's own directory of the server system, and deleting the files included in the list from the PDA.

- 12 -

4. A server system substantially as hereinbefore described with reference to figure 2 of the accompanying drawings.

- 5 5. A communication method substantially as hereinbefore described with reference to figures 3 and 4 of the accompanying drawings.
